

Executive Summary — scottyab/rootbeer Repository

Analysis Scope

This assessment uses the Part 2 repository-mining data to examine 67 files and 371 recorded file touches, focusing on development concentration, contributor activity, frequently modified files, and potential maintenance risks. The analysis combines file-level touch counts with contributor information and modification dates.

Key Findings

1. Development ownership is concentrated around a small number of contributors

Scott Alexander-Bown accounts for 154 of 371 recorded touches (41.5%), substantially more than any other contributor. The next largest contributor, Matthew Rollings, accounts for 67 touches (18.1%). Together, these two contributors represent nearly 60% of all recorded file modifications.

This concentration creates potential knowledge concentration risk, particularly if historically important contributors are no longer active. Several contributor identities also appear under similar names (for example, Matthew Rollings and matthew), meaning the actual concentration may be slightly understated due to author-name inconsistencies.

2. Recent repository activity appears focused on maintenance rather than broad feature development

The modification history shows substantial activity during 2015–2021, followed by a visible gap in the collected data before another burst of changes in 2024 and a small number of changes in 2026. The most recent recorded modifications affect files such as gradle.properties, CMakeLists.txt, and Const.java.

This pattern suggests the project may now be in a more mature maintenance phase, with recent work concentrated on configuration and compatibility updates rather than widespread changes across the codebase. Management should verify whether there is an active contributor pipeline for the core implementation, especially RootBeer.java.

Visualization: Source file commits over time

The scatter plot compares the weeks since the repository began (x-axis) with the total number of changes to source files (y-axis) in the scottyab/rootbeer repository.

This analysis measures file touches rather than code complexity, lines changed, or business impact. Therefore, these findings should be used as indicators for managerial review rather than definitive measures of productivity or code quality.
